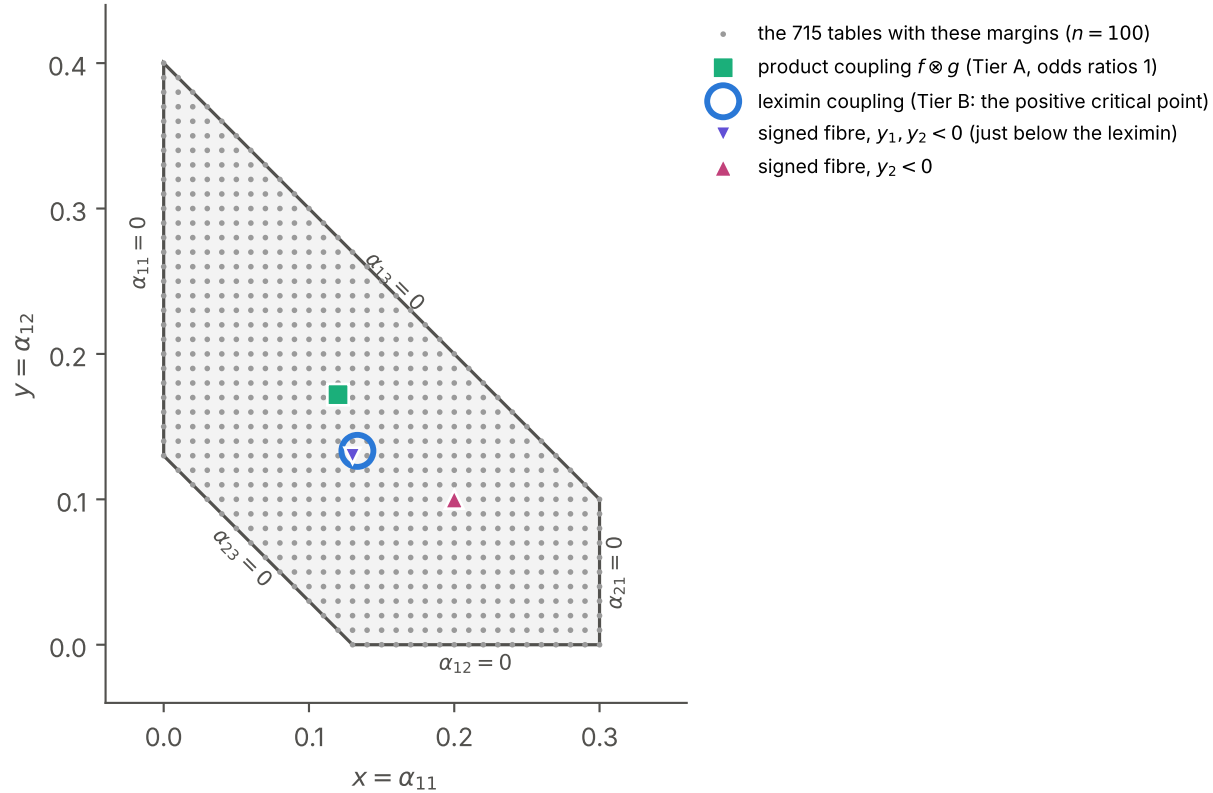
(a) The leximin coupling of f and g

cell 11 0.1333	cell 12 0.1333	cell 13 0.1333	$f_1 = 0.4$
cell 21 0.1667	cell 22 0.2967	cell 23 0.1367	$f_2 = 0.6$
$g_1 = 0.3$	$g_2 = 0.43$	$g_3 = 0.27$	

No coupling can have its smallest cell above $\min(f_i/3,\ g_j/2)$. Here row 1 is the scarcest per cell ($f_1/3 = 2/15$), so the best coupling spreads it evenly (shaded). This is the coupling that the positive critical point of W selects. Cell 23 is close behind ($g_3/2 = 0.135$): a near tie that section 11.5 exploits.


(b) The fibre Cpl(f, g): a pentagon whose sides are the cells that can vanish
